

# **COSC 3380**

## **Design of Database Systems**

### **Functional Dependencies and Normalization for Relational Databases**

March 27, 2024

# Guideline 1

- Design relation schema so that it is easy to explain its real-world meaning
- Do not combine attributes from multiple entity types and relationship types into a single relation

# Guideline 2

- Design base relation schemas so that no update anomalies are present in the relations
- If any anomalies are present:
  - Note them clearly
  - Make sure that the programs that update the database will operate correctly
  - Use triggers or stored procs for automatic updates

## Guideline 3

- Avoid placing attributes in a base relation whose values may frequently be NULL
- If NULLs are unavoidable:
  - Make sure that they apply in exceptional cases only, not to a majority of tuples

# Guideline 4

- Design relation schemas to be joined with equality conditions on attributes that are appropriately related
  - Guarantees that no spurious tuples are generated
- Avoid relations that contain matching attributes that are not (foreign key, primary key) combinations

# Generation of spurious tuples

# Guideline 4

- Design relation schemas to be joined with equality conditions on attributes that are appropriately related
  - Guarantees that no spurious tuples are generated
- Avoid relations that contain matching attributes that are not (foreign key, primary key) combinations

# Recap: Informal Design Guidelines

- Design relation schema so that it is easy to explain its real-world meaning
- Do not combine attributes from multiple entity types and relationship types into a single relation

- Avoid placing attributes in a base relation whose values may frequently be NULL
- If NULLs are unavoidable:
  - Make sure that they apply in exceptional cases only, not to a majority of tuples

- Design base relation schemas so that no update anomalies are present in the relations
- If any anomalies are present:
  - Note them clearly
  - Make sure that the programs that update the database will operate correctly
  - Use triggers or stored procs for automatic updates

- Design relation schemas to be joined with equality conditions on attributes that are appropriately related
  - Guarantees that no spurious tuples are generated
- Avoid relations that contain matching attributes that are not (foreign key, primary key) combinations

# Functional Dependency

- Constraint between two sets of attributes from the database

**Definition.** A functional dependency, denoted by  $X \rightarrow Y$ , between two sets of attributes  $X$  and  $Y$  that are subsets of  $R$  specifies a *constraint* on the possible tuples that can form a relation state  $r$  of  $R$ . The constraint is that, for any two tuples  $t_1$  and  $t_2$  in  $r$  that have  $t_1[X] = t_2[X]$ , they must also have  $t_1[Y] = t_2[Y]$ .

- Property of the semantics or meaning of the attributes

# Functional Dependency

- Y component of a tuple depends on or is determined by values of X component
- Values of X component of a tuple uniquely/functionally determine the values of Y component
- Y is functionally dependent on X

$$X \rightarrow Y$$

# Functional Dependency

- If  $X$  is a candidate key of relation,  $R$ 
  - Cannot be more than one tuple with a given  $X$  value
  - $X \rightarrow Y$  for any subset of attributes  $Y$  in  $R$
  - With  $X$  as candidate key,  $X \rightarrow R$
  - $X \rightarrow Y$  in  $R$  does not mean  $Y \rightarrow X$  in  $R$

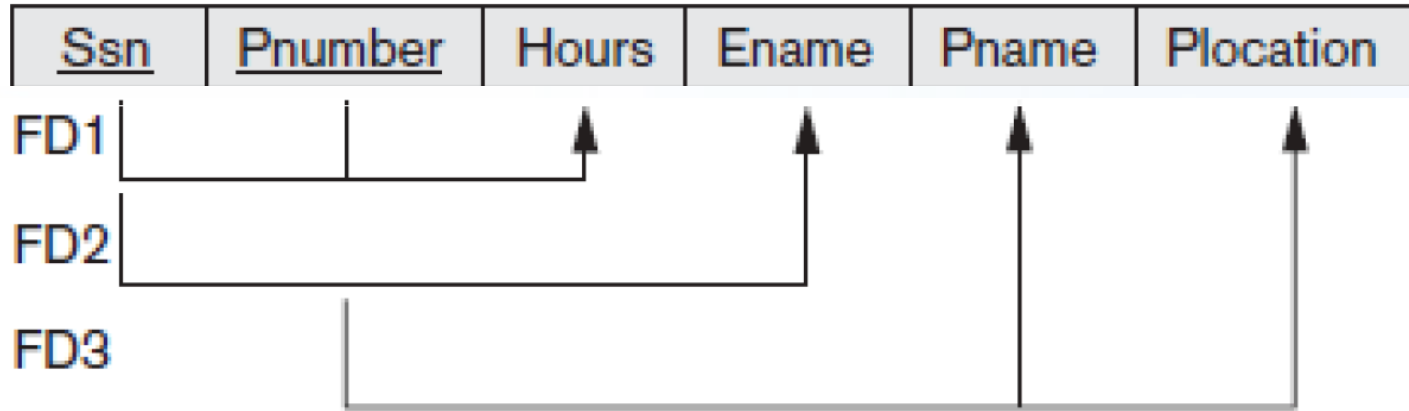

# Functional Dependency

- $X \rightarrow Y$  holds if whenever two tuples have the same value for  $X$ , they *must have* the same value for  $Y$ 
  - For any two tuples,  $t_1$  and  $t_2$ , in any relation instance  $r(R)$ : If  $t_1[X]=t_2[X]$ , *then*  $t_1[Y]=t_2[Y]$
- $X \rightarrow Y$  in  $R$  specifies a *constraint* on all relation instances  $r(R)$
- Can be displayed graphically on a relation schema
- FDs are derived from the real-world constraints on the attributes

# Functional Dependency

**EMP\_PROJ**

a.  $Ssn \rightarrow Ename$

b.  $Pnumber \rightarrow \{Pname, Plocation\}$

c.  $\{Ssn, Pnumber\} \rightarrow Hours$

# Functional Dependency

- A FD is a property of the attributes in the schema R
- The constraint must hold on *every* relation instance  $r(R)$
- If K is a key of R, then K functionally determines all attributes in R
  - As we never have two distinct tuples with  $t_1[K]=t_2[K]$

# Defining FDs from instances

- To define the FDs, we need to understand the meaning of the attributes involved and the relationship between them.
- Given the instance (population) of a relation, all we can conclude is that an FD may exist between certain attributes.
- What we can definitely conclude is – that certain FDs do not exist because there are tuples that show a violation of those dependencies.

# Functional Dependency

## TEACH

| Teacher | Course          | Text     |
|---------|-----------------|----------|
| Smith   | Data Structures | Bartram  |
| Smith   | Data Management | Martin   |
| Hall    | Compilers       | Hoffman  |
| Brown   | Data Structures | Horowitz |

TEXT  $\rightarrow$  COURSE

TEACHER  $\rightarrow$  COURSE

# What FDs may exist?

- A relation  $R(A, B, C, D)$  with its extension.

| A  | B  | C  | D  |
|----|----|----|----|
| a1 | b1 | c1 | d1 |
| a1 | b2 | c2 | d2 |
| a2 | b2 | c2 | d3 |
| a3 | b3 | c4 | d3 |

- Which FDs may exist in this relation?

# Normalization of Relations

- Normal forms are based on functional dependencies amongst the attributes of a relation
- Take a relation schema through a series of tests
  - Certify whether it satisfies a certain normal form
  - Proceed in a top-down fashion

# Normalization of Relations

- Analyze a given relation schema based on their FDs and primary keys
  - Minimize redundancy
  - Minimize insertion/deletion/update anomalies
- Filtering/purification process to achieve better quality design

# Normalization of Relations

**Definition.** The normal form of a relation refers to the highest normal form condition that it meets, and hence indicates the degree to which it has been normalized.

## Objectives of normalization:

1. To free the collection of relations from undesirable insertion, update and deletion dependencies;
2. To reduce the need for restructuring the collection of relations, as new types of data are introduced, and thus increase the life span of application programs;
3. To make the relational model more informative to users;
4. To make the collection of relations neutral to the query statistics, where these statistics are liable to change as time goes by.

— E.F. Codd, "Further Normalization of the Data Base Relational Model"<sup>[9]</sup>

# Normalization of Relations

- Properties of a normalized relational schema
  - Nonadditive/lossless join property
    - Ensures spurious tuples are not created with schemas created after decomposition
    - Extremely critical and must be achieved at any cost
  - Dependency preservation property
    - Each FD represented in some relation resulting after decomposition
    - Desirable but sometimes sacrificed due to other factors

# Practical Use of Normal Forms

- Normalization carried out in practice
  - Resulting designs are of high quality and meet the requirements/goals
  - Pays particular attention to normalization only up to 3NF, BCNF (3.5NF), or at most 4NF
- Do not need to normalize to the highest possible normal form!
- Denormalization

**Definition. Denormalization** is the process of storing the join of higher normal form relations as a base relation, which is in a lower normal form.

# Recall time!

- Candidate Key
- Primary Key
- Super Key
- A **Prime attribute** must be a member of *some* candidate key
- A **Nonprime attribute** is not a prime attribute—that is, it is not a member of any candidate key.

# First Normal Form

- Domain of an attribute must include only **atomic** (**simple, indivisible**) values
- Value of any attribute in a tuple must be a single value
- Disallows a set of values as an attribute value in a single tuple
  - Disallows composite attributes
  - Disallows multivalued attributes
  - Disallows relations within relations
- Most RDBMSs allow only those relations to be defined that are in 1NF

# First Normal Form
